

Eurex Clearing

Eurex Clearing Messaging Interfaces Connectivity
B: AMQP Programming Guide

Date	Rel.	Change
12 February 2021	7.1	Removed Qpid C++ from list of broker implementations (chapter 2) Removed information about temporary queues and AMQP 0-10 protocol (chapter 3.3.3.1)
28 May 2021	7.1	Added description of JMS Client ID uniqueness (chapter 3.3.2)
9 June 2021	8.0	No changes for C7 Release 8.0
7 Sept 2021	8.1	No change for C7 Release 8.1

Date	Vers.	Change
9 April 2025	1.1	Removed obsolete code examples and added Qpid Proton C++ example
12 May 2026	1.2	Deletion of chapter 5ff and 6

Eurex® 2026

Deutsche Börse AG (“DBAG”), Clearstream Europe AG (“Clearstream”), Eurex Frankfurt AG (“Eurex”), Eurex Clearing AG (“Eurex Clearing”), Eurex Repo GmbH (“Eurex Repo”) are corporate entities and are registered under German law. Eurex Global Derivatives AG is a corporate entity and is registered under Swiss law. Clearstream Banking S.A. is a corporate entity and is registered under Luxembourg law. Eurex Frankfurt AG is the administrating and operating institution of Eurex Deutschland. Eurex Deutschland is in the following also referred to as the “Eurex Exchange”.

All intellectual property, proprietary and other rights and interests in this publication and the subject matter hereof (other than certain trademarks and service marks listed below) are owned by DBAG or its affiliates and subsidiaries or used under authorization by their respective owners, including, without limitation, all patent, registered design, copyright, trademark and service mark rights. While reasonable care has been taken in the preparation of this publication to provide details that are accurate and not misleading at the time of publication DBAG, Clearstream, Eurex, Eurex Clearing, Eurex Repo as well as the Eurex Exchange and their respective subsidiaries, servants and agents (a) do not make any representations or warranties regarding the information contained herein, whether express or implied, including without limitation any implied warranty of merchantability or fitness for a particular purpose or any warranty with respect to the accuracy, correctness, quality, completeness or timeliness of such information, and (b) shall not be responsible or liable for any third party’s use of any information contained herein under any circumstances, including, without limitation, in connection with actual trading or otherwise or for any errors or omissions contained in this publication in so far as no willful violation of obligations took place or, as the case may be, no injury to life, health or body arises or claims resulting from the Product Liability Act are affected.

This publication is published for information purposes only and shall not constitute investment advice respectively does not constitute an offer, solicitation or recommendation to acquire or dispose of any investment or to engage in any other transaction. This publication is not intended for solicitation purposes but only for use as general information. All descriptions, examples and calculations contained in this publication are for illustrative purposes only.

Eurex, Eurex Clearing and Eurex Repo offer services directly to members of the Eurex Exchange respectively to clearing members of Eurex Clearing. Those who desire to trade any products available on the Eurex market or who desire to offer and sell any such products to others or who desire to possess a clearing license of Eurex Clearing in order to participate in the clearing process provided by Eurex Clearing, should consider legal and regulatory requirements of those jurisdictions relevant to them, as well as the risks associated with such products, before doing so.

Only Eurex derivatives that are CFTC-approved may be traded via direct access in the United States or by United States persons. A complete, up-to-date list of Eurex derivatives that are CFTC-approved is available at: www.eurex.com/ex-en/rules-regs/eurex-derivatives-us/direct-market-access-from-the-us.

In addition, Eurex representatives and participants may familiarize U.S. Qualified Institutional Buyers (QIBs) and broker-dealers with certain eligible Eurex equity options and equity index options pursuant to the terms of the SEC’s July 1, 2013 Class No-Action Relief. A complete, up-to-date list of Eurex options that are eligible under the SEC Class No-Action Relief is available at: www.eurex.com/ex-en/rules-regs/eurex-derivatives-us/eurex-options-in-the-us-for-eligible-customers. Lastly, U.S. QIBs and broker-dealers trading on behalf of QIBs may trade certain single-security futures and narrow-based security index futures subject to terms and conditions of the SEC’s Exchange Act Release No. 60,194 (June 30, 2009), 74 Fed. Reg. 32,200 (July 7, 2009) and the CFTC’s Division of Clearing and Intermediary Oversight Advisory Concerning the Offer and Sale of Foreign Security Futures Products to Customers Located in the United States (June 8, 2010).

Trademarks and Service Marks

Buxl®, DAX®, DivDAX®, eb.rexx®, Eurex®, Eurex Repo®, Strategy Wizard®, Euro GC®, FDAX®, FTSE 100, FWB®, GC Pooling®, GCPI®, MDAX®, ODAX®, SDAX®, TecDAX®, USD GC Pooling®, VDAX®, VDAX-NEW® and Xetra® are registered trademarks of DBAG or its affiliates and subsidiaries.

All rights in the FTSE®100 Index (the “Index”) vest in FTSE or its licensors. Neither FTSE nor any of their affiliates or licensors (a) assumes any liability, losses, damages, expenses or obligations in connection with any derivative product based on the Index; or (b) accepts any liability for any errors or omissions, fitness for a particular purpose or the results to be obtained from the use of the Index or related data. No party may rely on the Index or related data contained in this communication which Index and data is owned by FTSE or their affiliates. No use or distribution of the Index is permitted without FTSE’s express written consent. FTSE does not promote, sponsor or endorse the content of this communication nor any financial or derivative product that it relates to.

PRIIPs: Eurex Deutschland qualifies as manufacturer of packaged retail and insurance-based investment products (PRIIPs) under Regulation (EU) No 1286/2014 on key information documents for packaged retail and insurance-based investment products (PRIIPs Regulation), and provides key information documents (KIDs) covering PRIIPs traded on Eurex Deutschland on its website under the following link: www.eurex.com/ex-en/rules-regs/priips-kids.

In addition, according to Art. 14(1) PRIIPs Regulation the person advising on, or selling, a PRIIP shall provide the KID to retail investors free of charge.

Abstract

This document provides information about the connectivity for the AMQP based Eurex Clearing FIXML Interface, Eurex Clearing FpML Interface and Eurex Clearing Margin Calculator Interface. This document is intended to be a guide to Members developing applications, which will utilize this interface.

1 Introduction

1.1 Overview

1.1.1 Eurex Clearing FIXML Interface

The Eurex Clearing FIXML Interface provides Eurex Clearing Members with a highly flexible, standards compliant and cost-effective way to use Eurex Clearing services. Based on this interface, Members are allowed to choose and deploy their own operating systems and access interfaces.

1.1.2 Eurex Clearing FpML Interface

The Eurex Clearing FpML Interface provides EurexOTC Members with a highly flexible, standards compliant and cost-effective way to use EurexOTC Clear services. Based on this interface, Members are allowed to choose and deploy their own operating systems and access interfaces.

1.1.3 Eurex Clearing Margin Calculator Interface

The Eurex Clearing Margin Calculator Interface provides EurexOTC Members with a highly flexible, standards compliant and cost-effective way to use the EurexOTC Clear Margin Calculator service. Based on this interface, Members are allowed to choose and deploy their own operating systems and access interfaces.

1.1.4 Eurex Clearing Trade Entry Interface

The Eurex Clearing Trade Entry Interface provides EurexOTC Service Providers with a highly flexible, standards compliant and cost-effective way to use EurexOTC Clear services. Based on this interface, Approved Trade sources are allowed to choose and deploy their own operating systems and access interfaces.

1.1.5 AMQP

The Advanced Message Queuing Protocol (AMQP) constitutes the preferred transport layer for delivering messages. AMQP is an open standard with a specific focus on the financial services industry which can be used royalty free. Members can choose the platform and programming language for their client applications. More information is available at the AMQP homepage:

- <http://www.amqp.org/>

1.1.6 FIXML

Application layer messages on the Eurex Clearing FIXML Interface are based upon and compliant to the widely used FIX standard. FIXML is the XML vocabulary for creating Financial Information eXchange (FIX) protocol messages based on XML.

The Futures Industry Association (FIA)/Futures and Options Association (FOA) initiative for standardized post-trade processing has chosen FIX as the standard communication protocol. More information can be found here:

- <http://www.futuresindustry.org/downloads/FIMag/2007/Outlook/Outlook-Standards.pdf>

The specification of FIX 5.0 SP2 is provided here:

- <http://www.fixtradingcommunity.org/FIXimate/FIXimate3.0/>

To learn more about supported FIX/FIXML messages, please refer to “Volume 1: Overview” and volumes 3-5 which are available for download in the public section of the Eurex Clearing website.

1.1.7 FpML

Application layer messages on the Eurex Clearing FpML Interface are based upon and compliant to the widely used FpML standard. FpML – Financial products Markup Language – is the industry standard for complex financial products which is based on XML.

The specification for FpML 5.6 is provided here:

- <http://www.fpml.org>

To learn more about supported XML/FpML messages, please refer to “Volume 1: Overview” and “Volume 3: Trade Notification & Take-up Confirmation”, and “Volume 3-A: Post Trade Events” which is available for download in the Member Section of the Eurex Clearing website.

1.2 Intended audience

This document is intended for system designers and programmers who wish to develop/adapt their client application to interact with the services offered by the Eurex Clearing FIXML Interface, the Eurex Clearing FpML Interface, the Eurex Clearing Margin Calculator Interface or Eurex Clearing Trade Entry Interface.

This Programming Guide expects the knowledge of the Eurex Clearing FIXML Interface Specification or of the Eurex Clearing FpML Interface.

1.3 Eurex Clearing Messaging Interface Connectivity documentation

The Eurex Clearing FIXML, FpML, Margin Calculator and Trade Entry Interfaces share common connectivity documents for AMQP and WebSphere MQ:

- A: Overview
- **B: AMQP Programming Guide** (this document)
- E: AMQP Setup and Internals

All “Eurex Clearing Interfaces – Connectivity” documents are available for download on the Eurex Clearing website under the following paths:

For Eurex Clearing’s C7:

<https://www.eurex.com/ec-en/>

Support > Technology > C7 > Supporting documents

Simplified (especially error & exception handling and logging) code examples to provide better overview of the functionality are available for download on GitHub.

- <https://github.com/Eurex-Clearing-Messaging-Interfaces>

1.4 Eurex Clearing FIXML Interface documentation

The Eurex Clearing FIXML Interface documentation is organized as follows:

- Volume 1: Overview
- Volume 3: Transaction & Position Confirmation
- Volume 4: Transaction & Position Maintenance
- Volume 5: Public Broadcasts
- Volume 6: Message Samples

All documents and the public keys of the AMQP broker are available for download in the public section of the Eurex Clearing website under the following paths:

For Eurex Clearing’s C7:

<https://www.eurex.com/ec-en/>

Support > Initiatives & Releases > C7 Releases > C7 Release XX > Interfaces

<https://www.eurex.com/ec-en/>

Support > Technology > C7 > Supporting documents

1.5 Eurex Clearing FpML Interface, Margin Calculator Interface and Trade Entry Interface documentation

The Eurex Clearing FpML Interface, Eurex Clearing Margin Calculator Interface and Eurex Clearing Trade Entry Interface documentation is organized as follows:

- Volume 1: Overview
- Volume 3: Trade Notification & Take-Up Confirmation
- Volume 3-A: Post Trade Events
- Volume 3-B: EurexOTC Eurex FpML API for Trade Entry
- Volume 3-C: EurexOTC Clear Margin Calculator Interface

All documents and the public keys of the AMQP brokers are available for download in the Member Section of the Eurex Clearing website under the following path:

<https://membersection.deutsche-boerse.com>

<https://www.eurex.com/ec-en/>

Support > Technology > C7 > Supporting documents

1.6 Conventions used in this document

- **Cross references** to other chapters within this document are always clickable, but not marked separately.
- **Hyperlinks to websites** are underlined.

1.7 Examples used in this document

The Member ABCFR and the Eurex Clearing FIXML/FpML/Margin Calculator Interface account ABCFR_ABCFRALMMACC1 are used in the examples in all chapters of this document.

1.8 Organization of this document

- Chapter 2 – Obtaining the AMQP Client API
 - Describes how the Apache Qpid client software can be obtained
- Chapter 3 – Java
 - Describes how to use the Java interface
- Chapter 4 – C++
 - Describes how to use the C++ interface
- Chapter 5 – .NET
 - Describes how to use the .NET interface
- Chapter 6 – Python

- Describes how to use the Python clients
- Chapter 7 – Troubleshooting
 - Describes typical problems
- Chapter 8 – Glossary of Terms and Abbreviations
 - Glossary of terms and abbreviations used through the document

1.9 Code examples

Simplified (especially error & exception handling and logging) code examples are available, to provide better overview of the functionality. The examples are available for download on GitHub:

<https://github.com/Eurex-Clearing-Messaging-Interfaces>

2 Obtaining the AMQP client API

The Eurex Clearing interfaces support only AMQP 1.0 protocol (ISO 19464).

There are multiple implementations of the AMQP protocol. AMQP brokers for Eurex Clearing interfaces are using the Apache Broker-J broker implementation. However, the Members are not obligated to use the client libraries provided by the same vendor as Eurex Clearing is using. Eurex clearing interfaces should be compatible with every AMQP client library which:

- Supports AMQP 1.0 protocol
- Supports TLS encryption
- Supports TLS client authentication and SASL EXTERNAL mechanism

Apache Qpid client libraries were tested for compatibility with Eurex Clearing interfaces.

2.1 Apache Qpid

Apache Qpid is an open source AMQP implementation licensed under the Apache License 2.0. More information can be found on the Qpid website: <http://qpid.apache.org>

The client libraries supporting AMQP 1.0 are available for multiple programming languages, including:

- C/C++
- C# .NET
- Java
- Python

The following components are expected to be compatible with Eurex Clearing interfaces:

- Qpid Proton C, C++, .NET, Python, Java
- Qpid JMS for AMQP 1.0 (Java, <http://qpid.apache.org/components/jms/index.html>)
- Qpid Messaging API (C++)
- Qpid Dispatch router (AMQP 1.0 only)

Members are free to choose any of the above-mentioned libraries according to their own requirements. The last versions tested for compatibility with Eurex Clearing interfaces are:

- Qpid Proton C and its C++ and Python bindings version 0.40.0
- Qpid JMS client 2.7.0
- Qpid Messaging C++ and Python client 1.39.0
- Qpid Dispatch router 1.19.0

The Apache Qpid project provides the documentation as well as API references for all of its components on its website (<http://qpid.apache.org/documentation.html>)

2.2 Upgrading client libraries

It is recommended to always use the last stable version available. New releases of the client libraries usually bring many updates and bug fixes. It is recommended to follow the development and regularly upgrade to the latest version.

3 Java

This chapter contains the guide through the development of Eurex Clearing interface client programs in Java.

3.1 SSL / TLS Certificates

Eurex Clearing interfaces are using TLS encryption and certificate based client authentication to ensure security. Both the public keys of the AMQP broker as well as the client certificate have to be provided to the client. Without them, the clients will be unable to connect / authenticate.

3.1.1 Client certificate

The guide for generating the client certificates is part of the "Volume A: Connectivity" document. Java clients require the client certificate to be provided in the PKCS12 format, where it is encrypted and protected by password. When using the keytool utility to generate the certificate, it will be created already in the PKCS12 format. In case other tools are used to generate the certificate, it must be converted first.

The keystore file needs to be provided to the Java client together with the password.

3.1.2 Broker public keys

When connecting to the broker, the Member application should verify the identity of the AMQP broker in order to protect against man in the middle attacks. The Eurex Clearing AMQP brokers use certificates signed by a trusted certification authority (CA). The public keys of Eurex Clearing interfaces can be used to verify their identity. Each interface has its own unique keys for simulation and production environments.

The public key(s) should be stored in a file called "truststore". The truststore is stored in Java Keystore (JKS) format, where it is encrypted and protected by password. The truststore file needs to be provided to the Java client together with the password. The truststore can contain multiple public keys.

The "Certificate Issuers" (i.e. DigiCert) "Root certificate" (i.e. DigiCert Global Root G2) and "CA certificate" (i.e. DigiCert Global ... CA1) can be added to the "truststore" instead to avoid the replacement of outdated "AMQP broker certificates".

The public keys of the AMQP broker are available on the website of Eurex Clearing under the following path:

Eurex Clearing FIXML Interface: <https://www.eurex.com/ec-en/>

Support > Technology > C7 > Supporting Documents > Messaging Interfaces Connectivity

Eurex Clearing FpML Interface: <https://www.eurex.com/ec-en/>

Support > Technology > C7 > Supporting Documents > Messaging Interfaces Connectivity

Eurex Clearing Margin Calculator Interface: <https://www.eurex.com/ec-en/>

Support > Technology > C7 > Supporting Documents > Messaging Interfaces Connectivity

Eurex Clearing Trade Entry Interface: <https://www.eurex.com/ec-en/>*Support > Technology > C7 > Supporting Documents > Messaging Interfaces Connectivity*

They can be easily loaded into a new truststore using import functionality of the keytool utility.¹

```
>keytool -importcert -file <Broker1 certificate> -alias simulation -  
keystore <Truststore filename>
```

```
Enter keystore password: <Password>  
Owner: CN=ecag-fixml-simul.deutsche-boerse.com  
Issuer: CN=VeriSign Class 3 Secure Server CA - G3  
Serial number: ad550000002b7f9b8f4f31234af  
Valid from: Tue Apr 15 18:35:26 CEST 2012 until: Sun Apr 14 18:35:26  
CEST 2014  
Certificate fingerprints:  
    MD5: 8F:AE:D7:14:CD:37:3F:3B:E8:E7:F2:42:F3:14:BE:4E  
    SHA1:  
94:52:92:97:7C:0A:D7:23:11:E6:43:69:B0:1F:C5:1B:9F:C2:D3:9B  
    Signature algorithm name: SHA1withRSA  
    Version: 3  
Trust this certificate? [no]: yes  
Certificate was added to keystore
```

The **<Broker1 certificate>** and **<Truststore filename>** as well as the **<Password>** values have to be replaced according to Member's environment. The resulting truststore file should contain the public keys of all brokers as trusted certificate entry:

```
>keytool -list -keystore <Truststore filename>  
Enter keystore password: <Password>
```

```
Keystore-Typ: jks  
Keystore-Provider: SUN
```

Your keystore contains 2 entries

```
simulation, 28.04.2011, trustedCertEntry,  
Certificate fingerprint (MD5):  
86:58:B9:E1:83:80:E6:68:63:7E:92:EA:30:4A:D5:91
```

```
production, 28.04.2011, trustedCertEntry,  
Certificate fingerprint (MD5):  
86:63:B9:EA:83:80:E6:6F:6C:AE:92:EB:40:A2:31:53
```

¹ See "Volume A: Connectivity" for more details about the keytool utility.

3.1.3 SSL / TLS debugging

In case of problems with the SSL / TLS connection, the applications using Apache Qpid Java API have a SSL debugging mode. This mode can be activated using the system property

```
-Djavax.net.debug=ssl:handshake:verbose
```

3.2 JMS

Some of the Java clients are based on Java Message Service (JMS). JMS is a message-oriented middleware API, which is a part of the Java Platform Enterprise Edition. More information about Java Message Service can be found at the Jakarta EE website - <https://jakarta.ee/specifications/messaging/3.1/jakarta-messaging-spec-3.1>.

The goal of this chapter is not to provide a comprehensive guide to JMS API, but to provide code snippets illustrating the work with the Eurex Clearing FIXML/FpML/Margin Calculator Interface in Java.

The details which are specific to the different JMS implementations will be described in the subsequent chapters.

3.2.1 Java Naming and Directory Interface (JNDI)

The JMS applications typically use the Java Naming and Directory Interface (JNDI) to obtain a connection factory, connection URI and message source / target addresses. The JNDI configuration might be kept separate from the application – for example stored in a properties file. But it can be also dynamically created *Properties* or *HashMap* object.

The JNDI properties are used by the client application to connect to the broker and send or receive messages. The connection factory name as well as the syntax of the connection URI and addresses are different for different APIs.

The properties file has to be loaded and processed into the application. The classes *Properties* (*java.util*) and *InitialContext* (*javax.naming*) will be used. The following example shows how to load the properties from a file:

```
Properties properties = new Properties();  
properties.load(new FileInputStream("<PropertiesFile>"));  
InitialContext ctx = new InitialContext(properties);
```

The *<PropertiesFile>* has to be replaced according to the Member's environment. As a result, an *InitialContext* object is created in variable *ctx* containing all JNDI resources defined in the properties file. The context will be used later to retrieve the connection string and the destinations.

3.2.2 Preparing connection and session

The connection (class `Connection` from `javax.jms`) is created using the `ConnectionFactory` class (`javax.jms`). The connection factory has to be initialized using the connection string from our context:

```
ConnectionFactory fact = (ConnectionFactory)ctx.lookup("connection");
```

The connection factory is used to create a connection:

```
Connection conn = fact.createConnection();
```

After these steps, the connection is created in the `conn` object and connects to the AMQP broker. However, it is in state `STOPPED`. The `STOPPED` state allows the applications to send messages, but not to receive them. In order to receive messages, the connection must be started^{3.2.4}. This gives the application enough time to prepare for receiving of messages (create receivers, queues, listeners, ...).

Using the prepared connection, a session can be created.² The session is an instance of class `Session` from package `javax.jms`:

```
Session sess  
= conn.createSession(false, Session.CLIENT_ACKNOWLEDGE);
```

The `Session.CLIENT_ACKNOWLEDGE` parameter is instructing the session that the acknowledgments of the messages will be done manually by the client application. In case the acknowledgement should be done automatically by the application, the `Session.AUTO_ACKNOWLEDGE` option should be used. Using auto-acknowledgements without transactions is not recommended (see Eurex Clearing FIXML/FpML/Margin Calculator Interface Specification, "Volume E: AMQP Setup & Internals" for more details about reliability).

A session should be used as a long-lasting resource and shouldn't be created too often. For instance, creating a new session for sending each message in a tight loop can result in following exceptions:

```
javax.jms.JMSException (Exception when sending message:timed out waiting for session to become open (state=DETACHED))
```

Instead, the application should create a session before entering the loop and re-use the session.

When using the Spring framework, the `SingleConnectionFactory` should not be used because it recreates `Session` and `Producer` each time a message is to be sent. Instead, for example the `CachingConnectionFactory` should be used. The `CachingConnectionFactory` keeps both `Session` and `Producer` created and attached.

² For more details about the differences and relationship between connection and session, please visit JMS documentation or AMQP specification.

3.2.3 Creating a receiver/sender

After the connection and session have been prepared, a receiver or producer can be prepared next. The producer is an instance of class `MessageProducer` (`javax.jms`). The producer can be created by the session, using the method `createProducer(...)`. The producer is always bound to a specific destination, queue or topic which can be created from the context which has been prepared in chapter **Error! Reference source not found.**:

```
Destination requestDest = (Destination)ctx.lookup("requestAddress");  
MessageProducer requestProducer = sess.createProducer(requestDest);
```

The message receiver is an instance of class `MessageConsumer`³ (`javax.jms`). The receiver is created in the same way as the producer. Just instead of using the session's `createProducer(...)` method, the method `createConsumer(...)` is used. The receivers for receiving responses or broadcasts are created in the same way. Just the destination (and the address which has been used to create the destination) is different:

```
Destination responseDest = (Destination)ctx.lookup("responseAddress");  
MessageConsumer responseConsumer = sess.createConsumer(responseDest);
```

When creating the consumer, you can also specify a selector to receive only selected messages. The selector can be either based on a message property or on a message application property. On the wire, the JMS selector is translated to AMQP filter, and the filtering of messages is done directly on the AMQP broker. The JMS selector follows the JMS syntax. You can filter based on application properties:

```
MessageConsumer responseConsumer = sess.createConsumer(responseDest,  
"BusinessDate='20160813'");
```

Or you can filter based on message properties – for example using JMS Correlation ID:

```
MessageConsumer responseConsumer = sess.createConsumer(responseDest,  
"JMSCorrelationID='" + correlationID + "'");
```

There are multiple methods to get the messages from the receiver. One of them is a usage of a message listener. Message listener is a special object, which implements the `MessageListener` interface from package `javax.jms`. In order to use the listener, it has to be registered with the producer. The registration can be done using the `setMessageListener(...)` method of the receiver:

```
responseConsumer.setMessageListener(new Listener());
```

The listener will be described in detail in chapter 3.2.6.3.

3.2.4 Starting the connection

With connection, session and receiver ready, the connection can be started:

³ The JMS and AMQP are using slightly different terminology. The JMS term Consumer corresponds to the AMQP term receiver.

```
conn.start();
```

Only when the connection is started, can the application receive messages from the AMQP broker. If the application is intended to only send messages, the start of the connection is not necessary.

3.2.5 Thread safety

The JMS Session object is not thread safe. Since a `MessageProducer/MessageConsumer` is bound to a Session it cannot be used from more than one thread at the same time. For multi-thread access it is necessary to use a separate session (and underlying objects) from each thread.

3.2.6 Receiving/sending messages

3.2.6.1 Preparing a request message

To prepare a new message, the `TextMessage` class (`javax.jms`) can be used. For request messages, only the message body and the reply to key have to be filled. The message body can be entered when a new message is constructed, using the session's method `createTextMessage(...)`. After preparing the message, the reply to destination, queue or topic can be assigned to it. As before, the destination for the reply to parameter is created from the context object. With the destination being ready, the method `setJMSReplyTo(...)` can be used to assign it to the message.

```
TextMessage message = sess.createTextMessage("<FIXML>...</FIXML>");  
Destination replyDest = (Destination)ctx.lookup("replyAddress");  
message.setJMSReplyTo(replyDest);
```

3.2.6.2 Sending a request message

The message prepared in the previous chapter can be sent using the message producer. Since the producer has been initialized with the destination already at the beginning, it is not necessary to use the request destination again:

```
requestProducer.send(message);
```

Depending on the specific client, the messages might be by default sent synchronously or asynchronously.

The request queues have only limited capacity and when the queue is almost full a flow control mechanism will be activated by the broker (the exact queue sizes as well as the flow control thresholds for different interfaces can be found in Volume E of this documentation). When the flow control is activated for the given request queue, the broker will delay sending the confirmations of received messages. However, the flow control support in the Java JMS API is only limited and when the flow control is activated the client will only wait for a certain time and afterwards the send call fails with an exception. When sending the messages asynchronously, the client will continue sending messages and can exceed the queue capacity despite the flow control.

The recommended way to ensure the queue capacity will not be exceeded in Java JMS client is to track the number of outstanding requests (requests which were sent and not yet responded to) within the application and stop sending messages when the number of outstanding requests reaches the flow control threshold.

3.2.6.3 Receiving a message using Message listener

Message listener can be every object which implements the `MessageListener` interface (`javax.jms`). The assignment of the listener to the receiver is described in chapter 3.2.3. The `MessageListener` interface has only one method, called `onMessage(...)`. This method is called whenever the receiver receives a new message. The message is passed to the `onMessage()` method as a parameter and can be either processed inside of the method or passed to another object. In case the session has been created with manual acknowledgements, the message should be acknowledged after its processing is finished (see chapter 3.2.2 for more details). The acknowledgement can be done using the call of the `acknowledge()` method of the message. When using auto-acknowledgements, it is not necessary to acknowledge the message manually. One listener object can be used by multiple receivers.

```
public class Listener implements MessageListener
{
    public void onMessage(Message msg) {
        // Processing of the message
        try {
            // Acknowledging the message manually
            msg.acknowledge();
        } catch (JMSEException e) {
            // Handling the exception
        }
    }
}
```

Please note, that the JMS Session object is not thread safe. Therefore, it should not be used concurrently from multiple threads. If it is planned to receive concurrently messages from multiple sources, then one should create different sessions and create for each session one `MessageConsumer`, since the `MessageConsumer` is created and assigned to one session only.

Afterwards, each `MessageListener` will then be assigned to different `MessageConsumers` and therefore to different `Sessions`.

Using single session for multiple `MessageConsumers` has the effect that all calls to their `onMessage()` methods are serialized and the parallel message consuming is not used.

The message listener is used in the broadcast receiver example.

3.2.6.4 Receiving a message using the `receive()` method

Messages can be also received using the `receive()` method of the `MessageConsumer` instance:

```
Message msg = responseConsumer.receive();  
// Processing of the message  
msg.acknowledge();
```

Using parameters of the `receive()` method, the application can either wait until a message is received for a limited (pass the timeout in milliseconds as a parameter to the method) or unlimited time. Using the method `receiveNowait()`, a message can be received without waiting (if there is no message waiting, the method will return null).

In case the session has been created with manual acknowledgements, the message should be acknowledged after its processing is finished (see chapter 3.2.2 for more details). The acknowledgement can be done using the call of the `acknowledge()` method of the message. When using auto-acknowledgements, it is not necessary to acknowledge the message manually.

The `receive()` method is used in the response receiver example.

3.2.6.5 Message processing

The received message is returned from the `receive()` method or passed to the `onMessage()` listener method as an instance of the more generic class `Message` (`javax.jms`). To process the message, it must be casted either to `TextMessage` or the `ByteMessage`. The JMS API decides based on the message payload and message properties whether the message will be handled as `TextMessage` or `BytesMessage`. The messages received on Eurex Clearing interfaces might be presented in both types, depending on the message sender and the exact content.

With an instance of `TextMessage` class, it is easy to retrieve the message body. The method `getText(...)` will return the body as a `String` object. `ByteMessage` has the methods `getBodyLength()` and `readByte()`, which can be used to read the message body byte by byte. Since the FIXML/FpML/Margin Calculator response or broadcast messages are text based, the byte content has to be transformed to a string using a `StringBuilder` class.

```
if (msg instanceof TextMessage)
{
    TextMessage textMessage = (TextMessage) msg;
    messageText = textMessage.getText();
    // process the message body
}
else if (msg instanceof BytesMessage)
{
    BytesMessage bytesMessage = (BytesMessage) msg;
    StringBuilder builder = new StringBuilder();

    for (int i = 0; i < bytesMessage.getBodyLength(); i++) {
        builder.append((char)bytesMessage.readByte());
    }

    // process the message body
}
else
{
    // Unexpected message delivered
}
```

All other message attributes can be retrieved using the usual getter methods.

3.2.7 Closing the connection

When the application is exiting, it should properly close all AMQP related objects. The receivers, producers, session and connection all have a method `close()`, which will properly close them:

```
responseConsumer.close();
requestProducer.close();
sess.close();
conn.close();
```

3.2.8 Error handling

In JMS the errors are handled by catching the proper exceptions. The errors are either synchronous (e.g. creating the session fails) or asynchronous (e.g. the connection to the broker is lost as the client is waiting for messages). This chapter explains how to properly handle and recover from such situations.

A client application should be designed in a way that it is resilient to the above errors, it doesn't get stuck when error occurs and at the same time it doesn't start consuming more and more resources. The main building blocks for each client application are (starting from the top) a connection, session and receiver/sender. Closing a session automatically closes all receivers/senders beneath it and closing a connection automatically closes all underlying sessions.

A typical way of handling the chain of creating the producer/consumer may look like:

```
try {
    connection = fact.createConnection();
    session = connection.createSession(false,
                                       Session.CLIENT_ACKNOWLEDGE);
    Destination requestDestination = (Destination)
                                     ctx.lookup("requestAddress");
    MessageProducer requestProducer;
    requestProducer = session.createProducer(requestDestination);
} catch (JMSEException e) {
    e.printStackTrace();
} finally {
    connection.close();
}
```

In the above example we omitted the creation of the context and connection factory for better readability. Creation of the connection, session or message producer can result in failure and in that case an exception is thrown. In the catch block, we print the stack trace and continue with a final block by closing the connection, which is executed also in the case when try block finished without any failure.

The *JMSEException* is the root class for exceptions thrown by JMS API methods. Catching *JMSEException* provides a generic way of handling all exceptions related to the JMS API. One can catch the subclasses of this exception (e.g. *IllegalStateException*, *InvalidDestinationException*) which are described in the JMS API documentation. In some cases, depending on the type of error, it is not necessary to close the whole connection, but only the session and/or restart the producer/consumer. However, the JMS doesn't define what happens in terms of connection preservation in each case; neither there is a straightforward way of checking whether the connection or session is still valid. Closing and restarting the connection can be therefore considered as the safest option.

The above example illustrates how to catch exceptions synchronously, i.e. when some particular JMS API method fails.

For applications with only asynchronous message consumers, there exists an `ExceptionListener` interface behavior as follows. If a JMS provider detects a serious problem with a `Connection` object, it informs the `Connection` object's `ExceptionListener`, if one has been registered. It does this by calling the listener's `onException` method, passing it a `JMSException` argument describing the problem. In practice, when an exception listener is called, the connection is broken, and the JMS service is no longer available for the connection.

The example source codes present the way to register the `ExceptionListener` and how to notify the main thread in case an asynchronous exception occurs. Such a class has to implement the `ExceptionListener` interface and override the `onException` method. Afterwards, the instantiated class can be registered using `Connection`'s `setExceptionListener` method.

Generally, the client application should properly check all JMS API methods for exceptions and in case the exception occurred, an application can, at a minimum, log the problem and clean up its resources. An application can also notify any interested parties that need to be notified of such a problem. An application should be designed with a clean initialization setup, so it would be feasible to reinitialize the JMS objects when the exception occurs (either synchronous or asynchronous).

3.3 Apache Qpid JMS client for AMQP 1.0

3.3.1 Connection Factory

The Apache Qpid JMS client for AMQP 1.0 has its own connection factory, which is used to resolve the JNDI properties. The properties file has to contain the identification of the context factory:

```
java.naming.factory.initial=org.apache.qpid.jms.jndi.JmsInitialContextFactory
```

3.3.2 Connection URI

The connection URI specifies where the AMQP client should connect and what connection parameters should be used. In the JNDI properties, the connection URI should be placed like this:

```
connectionfactory.[jndiname]=<ConnectionURL>
```

for example:

```
connectionfactory.connection=<ConnectionURL>
```

For connecting to Eurex Clearing interfaces the connection string needs to specify:

- The correct IP address/hostname of the broker
- The correct port of the broker
- The path to the keystore with the client certificate
- Alias of the member certificate in the keystore

- The path to the truststore with the broker public keys
- Passwords for the keystore and truststore
- Idle timeout

The connection URI has a following format:

```
amqp://hostname:port[?option=value[&option2=value...]]
```

or for SSL connections:

```
amqps://hostname:port[?option=value[&option2=value...]]
```

The options needed to connect to the Eurex AMQP Interfaces are:

- `jms.clientID`
- `transport.trustStoreLocation`
- `transport.trustStorePassword`
- `transport.keyStoreLocation`
- `transport.keyStorePassword`
- `transport.keyAlias`
- `amqp.idleTimeout`

Example connection string:

```
amqps://<Hostname>:<Port>?jms.clientID=<ClientID>&transport.trustStoreLocation=<PathToTruststore>&transport.trustStorePassword=<TruststorePassword>&transport.keyStoreLocation=<PathToKeystore>&transport.keyStorePassword=<KeystorePassword>&transport.keyAlias=<KeystoreAlias>&amqp.idleTimeout=<HeartbeatInterval>
```

The client ID is the unique identifier of a member application and can be defined according to the Member's needs. Multiple connections with the same client ID will be refused. The client ID, if used, must be unique across all the connections of the broker (FIXML/FpML/Margin Calculator/Trade Entry). This limit applies per broker.

Idle timeout needs to be specified in number of milliseconds. If not used than the Qpid JMS client is using default idle timeout / heartbeat of 60000 milliseconds. The recommended `idleTimeout` interval is between 30000 and 120000 milliseconds.

An example connection string for the Eurex Clearing FIXML Interface may then look like this:

```
amqps://ecag-fixml-simul.deutsche-boerse.com:10170?jms.clientID=my-test-client1&transport.trustStoreLocation=truststore.jks&transport.trustStorePassword=123456&transport.keyStoreLocation=ABCFR_ABCFRALMMACC1.keystore&transport.keyStorePassword=123456&transport.keyAlias=abcf_r_abcf_ralmmacc1&amqp.idleTimeout=60000
```

Additional connection options can be found in the documentation on <http://qpid.apache.org/documentation.html>

The client supports automatic failover / reconnect. To enable the failover, the connection URI has to be wrapped into a *failover* prefix. The options starting with “jms.” Should be used outside of the failover enclosure while the other options (e.g. starting with “amqp.” or “transport.”) should stay inside. Alternatively, the other options can be used outside of the failover enclosure with the prefix “failover.nested.” – such options would apply to all brokers.

```
failover:(amqps://hostname:port[?option=value[&option2=value...]])[?failoverOption=value[&failoverOption2=value...][&jmsOption=value...][&nestedOption=value...]]
```

The failover supports among other following options:

- failover.reconnectDelay
- failover.maxReconnectAttempts
- failover.useReconnectBackOff
- failover.reconnectBackOffMultiplier

These options can be used to control how many times and in which time intervals the client should try to reconnect to the broker. For example:

```
failover:(amqps://ecag-fixml-simul.deutsche-boerse.com:10170?...)?failover.reconnectDelay=30000&failover.maxReconnectAttempts=10&failover.useReconnectBackOff=false&jms.clientID=myClient&failover.nested.amqp.idleTimeout=60000
```

Additional failover options can be found in the documentation on <http://qpid.apache.org/documentation.html>

3.3.3 Addresses

Addresses are used to describe the message target or message source.⁴ The address is a string, which is passed as a parameter to a receiver or a sender, where it is handled. An address always resolves to a node – either queue or topic. This chapter will focus on the specific address strings, which can be used to interact with the Eurex Clearing interfaces.

Every application needs 4 different address string types in order to fully utilize the Eurex Clearing interfaces:

1. Receiving broadcasts
2. Receiving responses
3. Sending requests
4. “ReplyTo” address in requests

In the JNDI properties, the type *queue* should be used for receiving messages (broadcast address and response address) and the type *topic* for sending messages (reply address and request address):

⁴ Client APIs from other providers will use a different approach for defining message targets and sources. Please refer to the documentation of the used API for more details.

```
queue.[jndiname]=<Address>
```

```
topic.[jndiname]=<Address>
```

for example:

```
topic.requestAddress=<Address>
```

```
queue.responseAddress=<Address>
```

3.3.3.1 Receiving responses to requests

As described in the Eurex Clearing FIXML/FpML/Margin Calculator Interface Specification, “Volume E: AMQP Setup & Internals”, receiving responses to requests can be done either using an auto-delete response queue which must be created by the client application and bound to the response exchange or using the predefined response queue.

The following address string can be used as a template:

<**ResponseQueueName**>

The placeholders in this template must be replaced with the appropriate values:

```
queue.responseAddress=response.ABCFR_ABCFRALMMACC1
```

3.3.3.2 Sending requests

The request messages should be sent to the request exchange, which is specific for each Member. Since the request exchange is already predefined, the address string is simpler than the address string for receiving responses:

<**RequestExchange**>

The placeholders in this template have to be replaced with the appropriate values:

```
topic.requestAddress=request.ABCFR_ABCFRALMMACC1
```

3.3.3.3 “ReplyTo” address in requests

The “ReplyTo” address is assigned as a property to the request message. It encodes both the reply to exchange as well as the reply to routing key:

<**ResponseExchange**>/<**ResponseRoutingKey**>

The placeholders in this template must be replaced with the appropriate values:

```
topic.replyAddress=response/response.ABCFR_ABCFRALMMACC1
```

The response to a request message sent with the reply to address above can be received by a receiver created using the example address from chapter **Error! Reference source not found.**

3.3.3.4 Receiving broadcasts

To receive broadcast messages, it is necessary to create a receiver on the broadcast queues predefined during the technical maintenance. The following address string can be used as a template:

`<PredefinedBroadcastQueue>`

The `<PredefinedBroadcastQueue>` placeholder has to be replaced by the real name of the Members' broadcast queue. The address string corresponding to the queue for the trade confirmation broadcast stream of Member ABCFR, account ABCFR_ABCFRALMMACC1 will be as follows:

```
queue.responseAddress=broadcast.ABCFR_ABCFRALMMACC1.TradeConfirmation
```

3.3.4 Performance

3.3.4.1 Receive pre-fetching

AMQP brokers typically push messages to client consumers without explicit client requests (asynchronously, in the background) up to a certain number of unsettled messages. The next time a message would be passed on to the application code, it is usually taken from this buffer (avoiding synchronous I/O). This buffering capacity of a client is configurable, and it is typically set to hundreds of messages by default. Setting it too low can have a negative impact on message throughput (less overlap of message processing and background I/O). Setting it too high can have a negative impact on client memory consumption (pre-fetch buffers need to hold many messages). Also, all messages pre-fetched by one consumer are "locked" to that consumer (and will not be delivered to any other consumer reading the same queue) until the consumer releases/rejects them. This can lead to a less-than-ideal load balancing in case of parallel consumption and processing of messages from a single broker queue.

In Apache Qpid JMS client for AMQP 1.0 client, the pre-fetch capacity can be specified in the connection address string using several options. For receiving from queues, following two options are relevant:

- `jms.prefetchPolicy.queuePrefetch`
- `jms.prefetchPolicy.all`

The default prefetch limit is set to 1000. Additional prefetch options can be found in the documentation on <http://qpid.apache.org/documentation.html>

3.3.4.2 Message acknowledgement

Message acknowledgement is synchronous by default. In case a client application requires asynchronous message acknowledgement (e.g. doesn't require guarantee that the acknowledged message was removed from a broker queue before proceeding further), it can be enabled using the "jms.sendAcksAsync" connection option.

When using explicit acknowledgement of received messages, doing one-by-one synchronous acknowledgement of messages can severely degrade performance. Message consumption rate is then limited by the network round-trip latency between the client and the broker. For example, a round-trip time of 100ms would limit the synchronous throughput to no more than 10 messages per second.

Message receiving performance in the synchronous acknowledge mode can be improved via block processing of messages. The following Java code example 3.2.6.4 illustrates block processing. It will receive and process up to 100 messages, then finally acknowledge all received messages in a single call (thus mitigating the impact of network latency):

```
int maxCount = 100;
Message message, lastMessage = null;
// receive and process up to 100 messages
while ((message = responseConsumer.receiveNoWait()) != null) {
    // process the message
    System.out.println(message.toString());
    // remember the last processed message
    lastMessage = message;
    // check total block size
    if (--maxCount <= 0) {
        break;
    }
}
// acknowledge ALL previously received messages
if (lastMessage != null) {
    lastMessage.acknowledge();
}
```

3.3.4.3 Sender synchronization

When sending messages (as shown in section 3.2.6.2), the send call is by default synchronous for messages which are persistent and are not part of a transaction. All other messages are sent asynchronously. Asynchronous sending means that a message being sent is not guaranteed to arrive at a broker by the time the send call returns in a client application. When a message is sent synchronously, the send call will wait for confirmation from the broker. However, sending messages synchronously can have a significant negative impact on performance in case of significant network latency between the client and the server.

Unlike in C++, it is not possible to invoke explicit session synchronization in JMS (to achieve block or batch sending and mitigate the negative impact of network latency).

The following options in the connection URI can be used to change this behavior:

- `.jms.forceAsyncSend`
- `.jms.alwaysSyncSend`

The option `.jms.alwaysSyncSend` can force the client to send all messages synchronously. The option `.jms.forceAsyncSend` does the exact opposite – it forces the client to send all messages asynchronously.

3.3.5 Logging

The Apache Qpid JMS client for AMQP 1.0 uses Simple Logging Facade for Java (SLF4J), which serves as a simple facade or abstraction for various logging frameworks. SLF4J allows the end-user to plug in the desired logging framework at deployment time. There is only a single mandatory dependency, namely **slf4j-api** library for using the client API.

According to the desired logging framework, one of the following SLF4J bindings can be included:

- **logback-classic** - A successor to the popular `log4j` project
- **slf4j-log4j12** - Binding for `log4j`, a widely used logging framework. Need to place `log4j.jar` on the class path.
- **slf4j-jdk14** - Binding for `java.util.logging`, also referred to as JDK 1.4 logging
- **slf4j-nop** - Binding for NOP, silently discarding all logging.
- **slf4j-simple** - Binding for Simple implementation, which outputs all events to `System.err`. Only messages of level INFO and higher are printed. This binding may be useful in the context of small applications.
- **slf4j-jcl** - Binding for Jakarta Commons Logging. This binding will delegate all SLF4J logging to JCL.

The simplest way to see the Java Qpid API log messages is to include the **slf4j-simple** binding library into the project path. All Qpid messages from level INFO and higher will be printed into the standard error output. To enable the logging of AMQP frames sent / received by the client, the Frame logger can be enabled by using following option in the connection URI:

```
amqp.traceFrames=true
```

Another option can be used to display the raw AMQP bytes which the client sends / receives:

```
amqp.traceBytes=true
```

4 C++ (Qpid Proton)

This chapter contains the guide through the development of Eurex Clearing FIXML/FpML/Margin Calculator Interface client programs in C++ language under the Linux operating system using the Apache Qpid Proton C++ API, version 0.40.0. The library is available for download at <http://qpid.apache.org>.

The code example is simplified (especially error & exception handling and logging) to provide a better overview of the functionality. This chapter will contain only code snippets.

4.1 Environment setup under Linux

To successfully connect to the Eurex Clearing FIXML/FpML/Margin Calculator Interface, the account certificate (public and private key) as well as a certificate for verification of the AMQP broker must be passed to the C++ Qpid Proton library.

1. Member's public key in a Base64-encoded PEM format according to RFC 1421 standard
<ABCFR_ABCFRALMMACC1>.crt
2. Member's private key in PEM format
<ABCFR_ABCFRALMMACC1>.key
3. Broker's public key in a Base64-encoded PEM format according to RFC 1421 standard
<Broker certificate>.crt

4.2 Simple AMQPs Client

The following code snippet shows how to create a simple AMQPs client using proton reactor pattern.

```
#include <proton/connection_options.hpp>
#include <proton/container.hpp>
#include <proton/message.hpp>
#include <proton/message_id.hpp>
#include <proton/messaging_handler.hpp>
#include <proton/receiver_options.hpp>
#include <proton/source_options.hpp>
#include <proton/ssl.hpp>
#include <proton/transport.hpp>
#include <proton/work_queue.hpp>

#include <iostream>

class amqps_client : public proton::messaging_handler
{
private:
    std::string url;
    proton::sender sender;
    proton::receiver receiver;

public:
    amqps_client(const std::string &url) : url{url} { }

    void on_container_start(proton::container &c) override
    {
        proton::ssl_certificate ssl_cert(
            "/path/to/ABCFR_ABCFRALMMACC1.crt",
            "/path/to/ABCFR_ABCFRALMMACC1.key",
            "password_to_client_private_key");
        proton::ssl_client_options sslopts(
            ssl_cert,
            "/path/to/broker_host_certificate.crt",
            proton::ssl::VERIFY_PEER);

        proton::connection_options c_opts;
        c_opts.ssl_client_options(sslopts).sasl_allowed_mechs("EXTERNAL");
        c_opts.virtual_host(url.c_str());
        c_opts.sasl_allow_insecure_mechs(false);
        c.client_connection_options(c_opts);

        sender = c.open_sender(url.c_str());

        proton::receiver_options r_opts =
proton::receiver_options().source(proton::source_options().dynamic(true));
        receiver = sender.connection().open_receiver("", r_opts);
    }

    void on_connection_open(proton::connection& c) override
    {
        std::cout << "Connected to: "
                  << c.url().c_str()
                  << std::endl;
    }

    void on_message(proton::delivery &d, proton::message &m) override
    {
        // Message is available.
    }
}
```

```
void on_transport_error(proton::transport &t) override
{
    std::cerr << "Transport error: "
               << t.error().what().c_str()
               << " "
               << "Connection: "
               << t.connection().url().c_str()
               << std::endl;
}

void send_message(const std::string &routing_key,
                 const std::string &message_content)
{
    proton::message message;

    message.id(proton::uuid::random());
    message.to(routing_key);
    message.body(message_content);

    message.reply_to(receiver.source().address());

    sender.work_queue().add( [= ] { sender.send(message); });
}

void disconnect()
{
    // Closing connection
    sender.work_queue().add( [= ] { sender.connection().close(); });
}

};
```

Proton AMQP client is using a reactor pattern which means all events are handled in internal event loop by calling appropriate callback method. Calling method **proton::container::run()** will start the event loop.

```
try
{
    amqps_client client("amqps://<IP/Hostname>:<Port>/<destination>");
    proton::container(client).run();
}
catch (const std::exception &e)
{
    std::cerr << e.what() << std::endl;
}
```

When a message is available the method **proton::messaging_handler::on_message()** is called. One possible way to send a message is to implement a new method **proton::messaging_handler::send_message()** which has access to **sender** object.

5 Troubleshooting

5.1 Errors

During a message exchange between a client and the broker several error situations may occur due to a misconfiguration or malfunctioning software.

5.1.1 Connection failure

The following reasons can lead to failure to establish a connection with the broker.

- Host unreachable
- Invalid host certificate
- Invalid client key

5.1.2 Too many connections

When the limit of maximum number of connections is reached.

```
Permission PERFORM_ACTION(connect) is denied for : VirtualHost 'default' on  
VirtualHostNode 'default' [condition = amqp:not-allowed]
```

5.1.3 Unknown destination

When a request is sent to an invalid address.

```
Unknown destination 'request.ABCFR_TESTCALMMACC1X' [condition = amqp:not-  
found]
```

5.1.4 Invalid destination

When a request is sent to an address to which the client does not have the right to publish.

```
Permission PERFORM_ACTION(publish) is denied for : Exchange  
'request.ABCFR_TESTCALMMACC2' on VirtualHost 'default' [condition = amqp:not-  
allowed]
```

5.1.5 Non-existent queue

Attempt to consume a message from a non-existent queue

```
Could not find destination for source  
'Source{address=broadcast.ABCFR_TESTCALMMACC1.PublicX,durable=none,expiryPolic  
y=link-  
detach,dynamic=false,defaultOutcome=Modified{deliveryFailed=true},outcomes=[am  
qp:accepted:list, amqp:released:list,  
amqp:rejected:list],capabilities=[queue]}' [condition = amqp:not-found]
```

5.1.6 Invalid queue

Attempt to consume a message from a queue which the client does not have the right to consume.

```
Permission CREATE is denied for : Consumer '17|1|qpId-  
jms:receiver:ID:bc025dfc-ac00-42aa-95d1-  
62f07dafa0ac:1:1:1:broadcast.ABCFR_TESTCALMMACC2.Public' on Queue  
'broadcast.ABCFR_TESTCALMMACC2.Public' [condition = amqp:unauthorized-access]
```

5.1.7 Full queue

5.1.7.1 Message count limit

When a request queue message count limit is reached.

```
Maximum depth exceeded on 'request_be.ABCFR_TESTCALMMACC1.C7' :  
current=[count: 6001, size: 4212630], max=[count: 6000, size: 6144000]  
[condition = amqp:resource-limit-exceeded]
```

5.1.7.2 Byte size limit

When a request queue byte size limit is reached.

```
Maximum depth exceeded on 'request_be.ABCFR_TESTCALMMACC1.C7' :  
current=[count: 4536, size: 6144580], max=[count: 6000, size: 6144000]  
[condition = amqp:resource-limit-exceeded]
```

5.2 Lost connection

It can happen that a connection between the broker and the client can be lost. To detect such failure client applications are advised to specify *idle-timeout* which will enable a *heart-beat* mechanism on the established connection. This way if a connection is lost both client and the broker can detect it and act accordingly.

In case of connection loss client can choose to reconnect automatically. If a connection loss is a result of a broker technical maintenance, it can be expected that the broker may not be available for several minutes. To cover such situation, it is suggested to automatically retry to connect every minute for at least 30 minutes.

6 Glossary of terms and abbreviations

<i>Term / Abbr.</i>	<i>Definition</i>
AMQP	Advanced Message Queuing Protocol - standard for Messaging Middleware.
Apache Qpid	Open source implementation of AMQP protocol
Binding	A binding is a relationship between a message queue and an exchange. The binding specifies routing arguments that tell the exchange which messages the queue should get.
Broker	AMQP middleware messaging server
Eurex System	Eurex hosts
Exchange	An exchange accepts messages from a producer application and routes them to message queues according to prearranged criteria.
EXTERNAL authentication	AMQP authentication mechanism based on SSL / TLS certificates
FIX	The Financial Information Exchange Protocol
FIXML	FIX business messages in XML syntax
FpML	Financial products Markup Language is the industry-standard protocol for complex financial products. It is based on XML.
Message	A message is the atomic unit of routing and queuing. Messages have a header consisting of a defined set of properties, and a body that is an opaque block of binary data.
Queue	A message queue stores messages in memory or on disk, and delivers these in sequence to one or more consumer applications. Message queues are message storage and distribution entities. Each message queue is entirely independent.
Routing key	A message property used in bindings to specify the exchange – queue relationship.
SASL	Simple Authentication and Security Layer
SSL	Secure Sockets Layer – cryptographic protocol designed to provide communication security over the Internet
TLS	Transport Layer Security – cryptographic protocol designed to provide communication security over the Internet and successor to SSL protocol.
XML	Extensible Markup Language
